MongoDB Tutorial
ABOUT THE TUTORIAL

MongoDB tutorial

MongoDB is an open-source document database, and leading NoSQL database. MongoDB is written in c++.

This tutorial will give you great understanding on MongoDB concepts needed to create and deploy a highly scalable and performance oriented database.

Audience

This tutorial is designed for Software Professionals who are willing to learn MongoDB Database in simple and easy steps. This tutorial will give you great understanding on MongoDB concepts and after completing this tutorial you will be at intermediate level of expertise from where you can take yourself at higher level of expertise.

Prerequisites

Before proceeding with this tutorial you should have a basic understanding of database, text editor and execution of programs etc. Because we are going to develop high performance database, so it will be good if you have understanding on basic concepts of Database (RDBMS).

MongoDB Deployment
MongoDB Overview

MongoDB is a cross-platform, document oriented database that provides, high performance, high availability, and easy scalability. MongoDB works on concept of collection and document.

Database
Database is a physical container for collections. Each database gets its own set of files on the file system. A single MongoDB server typically has multiple databases.

Collection
Collection is a group of MongoDB documents. It is the equivalent of an RDBMS table. A collection exists within a single database. Collections do not enforce a schema. Documents within a collection can have different fields. Typically, all documents in a collection are of similar or related purpose.

Document
A document is a set of key-value pairs. Documents have dynamic schema. Dynamic schema means that documents in the same collection do not need to have the same set of fields or structure, and common fields in a collection's documents may hold different types of data.

Below given table shows the relationship of RDBMS terminology with MongoDB

<table>
<thead>
<tr>
<th>RDBMS</th>
<th>MongoDB</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Database</td>
</tr>
<tr>
<td>Table</td>
<td>Collection</td>
</tr>
<tr>
<td>Tuple/Row</td>
<td>Document</td>
</tr>
<tr>
<td>column</td>
<td>Field</td>
</tr>
<tr>
<td>Table Join</td>
<td>Embedded Documents</td>
</tr>
<tr>
<td>Primary Key</td>
<td>Primary Key (Default key _id provided by mongodb itself)</td>
</tr>
</tbody>
</table>

Database Server and Client

<table>
<thead>
<tr>
<th>RDBMS</th>
<th>MongoDB</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql/Oracle</td>
<td>mongod</td>
</tr>
<tr>
<td>mysql/sqlplus</td>
<td>mongo</td>
</tr>
</tbody>
</table>
Sample document
Below given example shows the document structure of a blog site which is simply a comma separated key value pair.

```json
{
    _id: ObjectId('7df78ad8902c'),
    title: 'MongoDB Overview',
    description: 'MongoDB is no sql database',
    by: 'tutorialspoint',
    url: 'http://www.tutorialspoint.com',
    tags: ['mongodb', 'database', 'NoSQL'],
    likes: 100,
    comments: [
        {
            user: 'user1',
            message: 'My first comment',
            dateCreated: new Date(2011,1,20,2,15),
            like: 0
        },
        {
            user: 'user2',
            message: 'My second comments',
            dateCreated: new Date(2011,1,25,7,45),
            like: 5
        }
    ]
}
```

_id is a 12 bytes hexadecimal number which assures the uniqueness of every document. You can provide _id while inserting the document. If you didn't provide then MongoDB provide a unique id for every document. These 12 bytes first 4 bytes for the current timestamp, next 3 bytes for machine id, next 2 bytes for process id of mongodb server and remaining 3 bytes are simple incremental value.
MongoDB Advantages

Any relational database has a typical schema design that shows number of tables and the relationship between these tables. While in MongoDB there is no concept of relationship.

Advantages of MongoDB over RDBMS

- Schema less: MongoDB is a document database in which one collection holds different documents. Number of fields, content and size of the document can be different from one document to another.
- Structure of a single object is clear
- No complex joins
- Deep query-ability. MongoDB supports dynamic queries on documents using a document-based query language that's nearly as powerful as SQL
- Tuning
- Ease of scale-out: MongoDB is easy to scale
- Conversion / mapping of application objects to database objects not needed
- Uses internal memory for storing the (windowed) working set, enabling faster access of data

Why should use MongoDB

- Document Oriented Storage: Data is stored in the form of JSON style documents
- Index on any attribute
- Replication & High Availability
- Auto-Sharding
- Rich Queries
- Fast In-Place Updates
- Professional Support By MongoDB

Where should use MongoDB?

- Big Data
- Content Management and Delivery
- Mobile and Social Infrastructure
- User Data Management
- Data Hub
MongoDB Environment

Install MongoDB On Windows
To install the MongoDB on windows, first download the latest release of MongoDB from
http://www.mongodb.org/downloads Make sure you get correct version of MongoDB depending upon your windows
version. To get your windows version open command prompt and execute following command

```
C:\>wmic os get osarchitecture
OSArchitecture
64-bit
C:\>
```

32-bit versions of MongoDB only support databases smaller than 2GB and suitable only for testing and evaluation
purposes.

Now extract your downloaded file to c:\ drive or any other location. Make sure name of the extracted folder is
mongodb-win32-i386-[version] or mongodb-win32-x86_64-[version]. Here [version] is the version of MongoDB
download.

Now open command prompt and run the following command

```
C:\>move mongodb-win64-* mongodb
    1 dir(s) moved.
C:\>
```

In case you have extracted the mongodb at different location, then go to that path by using command cd
FOLDER/DIR and now run the above given process.

MongoDB requires a data folder to store its files. The default location for the MongoDB data directory is c:\data\db. So
you need to create this folder using the Command Prompt. Execute the following command sequence

```
C:\>md data
C:\md data\db
```

If you have install the MongoDB at different location, then you need to specify any alternate path for \data\db by
setting the path dbpath in mongod.exe. For the same issue following commands
In command prompt navigate to the bin directory present into the mongodb installation folder. Suppose my installation folder is **D:sset up:mongodb**

C:\Users\XYZ>d:
D:\>cd "set up"
D:\set up>cd mongodb
D:\set up.mongodb>cd bin
D:\set up\mongodb\bin>mongod.exe --dbpath "d:\set up\mongodb\data"

This will show **waiting for connections** message on the console output indicates that the mongod.exe process is running successfully.

Now to run the mongodb you need to open another command prompt and issue the following command

D:\set up\mongodb\bin>mongo.exe

MongoDB shell version: 2.4.6
connecting to: test
>db.test.save( { a: 1 } )
>db.test.find()
{ "_id" : ObjectID(5879b0f65a56a454), "a" : 1 }
>
This will show that mongodb is installed and run successfully. Next time when you run mongodb you need to issue only commands

D:\set up\mongodb\bin>mongod.exe --dbpath "d:\set up\mongodb\data"
D:\set up\mongodb\bin>mongo.exe

**Install MongoDB on Ubuntu**

Run the following command to import the MongoDB public GPG Key:

```sh
sudo apt-key adv --keyserver hkp://keyserver.ubuntu.com:80 --recv 7F0CEB10
```

Create a `/etc/apt/sources.list.d/mongodb.list` file using the following command.

```sh
echo 'deb http://downloads-distro.mongodb.org/repo/ubuntu-upstart dist 10gen' | sudo tee /etc/apt/sources.list.d/mongodb.list
```
Now issue the following command to update the repository:

```
sudo apt-get update
```

Now install the MongoDB by using following command:

```
apt-get install mongodb-10gen=2.2.3
```

In the above installation 2.2.3 is currently released mongodb version. Make sure to install latest version always. Now mongodb is installed successfully.

Start MongoDB

```
sudo service mongodb start
```

Stop MongoDB

```
sudo service mongodb stop
```

Restart MongoDB

```
sudo service mongodb restart
```

To use mongodb run the following command

```
mongo
```

This will connect you to running mongod instance.

**MongoDB Help**

To get list of commands type `db.help()` in mongodb client. This will give you list of commands as follows:
**MongoDB Statistics**

To get stats about mongodb server type the command `db.stats()` in mongod client. This will show the database name, number of collection and documents in the database. Output the command is shown below:
Data in MongoDB has a flexible schema. Documents in the same collection do not need to have the same set of fields or structure, and common fields in a collection’s documents may hold different types of data.

**Some considerations while designing schema in MongoDB**

- Design your schema according to user requirements.
- Combine objects into one document if you will use them together. Otherwise separate them (but make sure there should not be need of joins).
- Duplicate the data (but limited) because disk space is cheap as compare to compute time.
- Do joins while write, not on read.
- Optimize your schema for most frequent use cases.
- Do complex aggregation in the schema.

**Example**

Suppose a client needs a database design for his blog website and see the differences between RDBMS and MongoDB schema design. Website has the following requirements.

- Every post has the unique title, description and url.
- Every post can have one or more tags.
- Every post has the name of its publisher and total number of likes.
- Every Post have comments given by users along with their name, message, data-time and likes.
- On each post there can be zero or more comments.

In RDBMS schema design for above requirements will have minimum three tables.

While in MongoDB schema design will have one collection post and has the following structure:
So while showing the data, in RDBMS you need to join three tables and inmongodb data will be shown from one collection only.
MongoDB Create Database

**The use Command**

MongoDB `use DATABASE_NAME` is used to create database. The command will create a new database, if it doesn't exist otherwise it will return the existing database.

**Syntax:**

Basic syntax of `use DATABASE` statement is as follows:

```
use DATABASE_NAME
```

**Example:**

If you want to create a database with name `<mydb>`, then `use DATABASE` statement would be as follows:

```
>use mydb
switched to db mydb
```

To check your currently selected database use the command `db`

```
>db
mydb
```

If you want to check your databases list, then use the command `show dbs`.

```
>show dbs
local  0.78125GB
test   0.23012GB
```

Your created database (mydb) is not present in list. To display database you need to insert atleast one document into it.

```
>db.movie.insert({"name":"tutorials point"})
>show dbs
local  0.78125GB
mydb   0.23012GB
test   0.23012GB
```

In mongodb default database is test. If you didn't create any database then collections will be stored in test database.
**MongoDB Drop Database**

### The dropDatabase () Method

MongoDB `db.dropDatabase()` command is used to drop a existing database.

**Syntax:**

Basic syntax of `dropDatabase()` command is as follows:

```
db.dropDatabase()
```

This will delete the selected database. If you have not selected any database, then it will delete default 'test' database

**Example:**

First, check the list available databases by using the command `show dbs`

```
>show dbs
local      0.78125GB
mydb       0.23012GB
test       0.23012GB
>
```

If you want to delete new database `<mydb>`, then `dropDatabase()` command would be as follows:

```
>use mydb
switched to db mydb
>db.dropDatabase()
>{ "dropped" : "mydb", "ok" : 1 }
>
```

Now check list of databases

```
>show dbs
local      0.78125GB
test       0.23012GB
>
```
**MongoDB Create Collection**

**The createCollection() Method**

MongoDB `db.createCollection(name, options)` is used to create collection.

**Syntax:**

Basic syntax of `createCollection()` command is as follows

```
db.createCollection(name, options)
```

In the command, `name` is name of collection to be created. `Options` is a document and used to specify configuration of collection.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>String</td>
<td>Name of the collection to be created</td>
</tr>
<tr>
<td>Options</td>
<td>Document</td>
<td>(Optional) Specify options about memory size and indexing</td>
</tr>
</tbody>
</table>

Options parameter is optional, so you need to specify only name of the collection. Following is the list of options you can use:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>capped</td>
<td>Boolean</td>
<td>(Optional) If true, enables a capped collection. Capped collection is a collection fixed size collection that automatically overwrites its oldest entries when it reaches its maximum size. <strong>If you specify true, you need to specify size parameter also.</strong></td>
</tr>
<tr>
<td>autoIndexID</td>
<td>Boolean</td>
<td>(Optional) If true, automatically create index on _id field.s Default value is false.</td>
</tr>
<tr>
<td>size</td>
<td>number</td>
<td>(Optional) Specifies a maximum size in bytes for a capped collection. <strong>If capped is true, then you need to specify this field also.</strong></td>
</tr>
<tr>
<td>max</td>
<td>number</td>
<td>(Optional) Specifies the maximum number of documents allowed in the capped collection.</td>
</tr>
</tbody>
</table>

While inserting the document, MongoDB first checks size field of capped collection, then it checks max field.
Examples:

Basic syntax of `createCollection()` method without options is as follows:

```shell
> use test
switched to db test
> db.createCollection("mycollection")
{ "ok" : 1 }
>
```

You can check the created collection by using the command `show collections`:

```shell
> show collections
mycollection
system.indexes
```

Following example shows the syntax of `createCollection()` method with few important options:

```shell
> db.createCollection("mycol", { capped : true, autoIndexID : true, size : 6142800, max : 10000 } )
{ "ok" : 1 }
>
```

In `mongodb` you don't need to create collection. MongoDB creates collection automatically, when you insert some document:

```shell
> db.tutorialspoint.insert({"name" : "tutorialspoint"})
> show collections
mycol
mycollection
system.indexes
tutorialspoint
>
```
MongoDB Drop Collection

The drop() Method
MongoDB's `db.collection.drop()` is used to drop a collection from the database.

Syntax:
Basic syntax of `drop()` command is as follows

```
db.COLLECTION_NAME.drop()
```

Example:
First, check the available collections into your database `mydb`

```
>use mydb
switched to db mydb
>show collections
mycol
mycollection
system.indexes
tutorialspoint
>
```

Now drop the collection with the name `mycollection`

```
>db.mycollection.drop()
true
>
```

Again check the list of collections into database

```
>show collections
mycol
system.indexes
tutorialspoint
>
```

drop() method will return true, if the selected collection is dropped successfully otherwise it will return false
MongoDB Datatypes

MongoDB supports many datatypes whose list is given below:

- **String**: This is most commonly used datatype to store the data. String in mongodb must be UTF-8 valid.
- **Integer**: This type is used to store a numerical value. Integer can be 32 bit or 64 bit depending upon your server.
- **Boolean**: This type is used to store a boolean (true/ false) value.
- **Double**: This type is used to store floating point values.
- **Min/ Max keys**: This type is used to compare a value against the lowest and highest BSON elements.
- **Arrays**: This type is used to store arrays or list or multiple values into one key.
- **Timestamp**: ctimeststamp. This can be handy for recording when a document has been modified or added.
- **Object**: This datatype is used for embedded documents.
- **Null**: This type is used to store a Null value.
- **Symbol**: This datatype is used identically to a string however, it's generally reserved for languages that use a specific symbol type.
- **Date**: This datatype is used to store the current date or time in UNIX time format. You can specify your own date time by creating object of Date and passing day, month, year into it.
- **Object ID**: This datatype is used to store the document's ID.
- **Binary data**: This datatype is used to store binary data.
- **Code**: This datatype is used to store javascript code into document.
- **Regular expression**: This datatype is used to store regular expression.
**MongoDB - Insert Document**

**The insert() Method**

To insert data into MongoDB collection, you need to use MongoDB's `insert()` or `save()` method.

**Syntax**

Basic syntax of `insert()` command is as follows:

```
>db.COLLECTION_NAME.insert(document)
```

**Example**

```
>db.mycol.insert({
    _id: ObjectId(7df78ad8902c),
    title: 'MongoDB Overview',
    description: 'MongoDB is no sql database',
    by: 'tutorials point',
    url: 'http://www.tutorialspoint.com',
    tags: ['mongodb', 'database', 'NoSQL'],
    likes: 100
})
```

Here `mycol` is our collection name, as created in previous tutorial. If the collection doesn't exist in the database, then MongoDB will create this collection and then insert document into it.

In the inserted document if we don't specify the _id parameter, then MongoDB assigns an unique ObjectId for this document.

_id is 12 bytes hexadecimal number unique for every document in a collection. 12 bytes are divided as follows:

```
_id: ObjectId(4 bytes timestamp, 3 bytes machine id, 2 bytes process id, 3 bytes incrementer)
```

To insert multiple documents in single query, you can pass an array of documents in `insert()` command.

**Example**
> db.post.insert([
  {
    title: 'MongoDB Overview',
    description: 'MongoDB is no sql database',
    by: 'tutorials point',
    url: 'http://www.tutorialspoint.com',
    tags: ['mongodb', 'database', 'NoSQL'],
    likes: 100
  },
  {
    title: 'NoSQL Database',
    description: 'NoSQL database doesn't have tables',
    by: 'tutorials point',
    url: 'http://www.tutorialspoint.com',
    tags: ['mongodb', 'database', 'NoSQL'],
    likes: 20,
    comments: [
      {
        user: 'user1',
        message: 'My first comment',
        dateCreated: new Date(2013,11,10,2,35),
        like: 0
      }
    ]
  }
])

To insert the document you can use `db.post.save(document)` also. If you don't specify `_id` in the document then `save()` method will work same as `insert()` method. If you specify `_id` then it will replace whole data of document containing `_id` as specified in `save()` method.
MongoDB - Query Document

The find() Method

To query data from MongoDB collection, you need to use MongoDB’s find() method.

Syntax

Basic syntax of find() method is as follows

```bash
>db.COLLECTION_NAME.find()
```

find() method will display all the documents in a non-structured way.

The pretty() Method

To display the results in a formatted way, you can use pretty() method.

Syntax:

```bash
>db.mycol.find().pretty()
```

Example

```bash
>db.mycol.find().pretty()
{
   "_id": ObjectId(7df78ad8902c),
   "title": "MongoDB Overview",
   "description": "MongoDB is no sql database",
   "by": "tutorials point",
   "url": "http://www.tutorialspoint.com",
   "tags": ["mongodb", "database", "NoSQL"],
   "likes": "100"
}
```

Apart from find() method there is findOne() method, that reruns only one document.
RDBMS Where Clause Equivalents in MongoDB

To query the document on the basis of some condition, you can use following operations:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Syntax</th>
<th>Example</th>
<th>RDBMS Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equality</td>
<td><code>{&lt;key&gt;:&lt;value&gt;}</code></td>
<td><code>db.mycol.find({&quot;by&quot;:&quot;tutorials point&quot;}).pretty()</code></td>
<td>where <code>by = tutorials point</code></td>
</tr>
<tr>
<td>Less Than</td>
<td><code>{&lt;key&gt;:{$lt:&lt;value&gt;}}</code></td>
<td><code>db.mycol.find({&quot;likes&quot;:{&quot;$lt:50}}).pretty()</code></td>
<td>where <code>likes &lt; 50</code></td>
</tr>
<tr>
<td>Less Than Equals</td>
<td><code>{&lt;key&gt;:{$lte:&lt;value&gt;}}</code></td>
<td><code>db.mycol.find({&quot;likes&quot;:{&quot;$lte:50}}).pretty()</code></td>
<td>where <code>likes &lt;= 50</code></td>
</tr>
<tr>
<td>Greater Than</td>
<td><code>{&lt;key&gt;:{$gt:&lt;value&gt;}}</code></td>
<td><code>db.mycol.find({&quot;likes&quot;:{&quot;$gt:50}}).pretty()</code></td>
<td>where <code>likes &gt; 50</code></td>
</tr>
<tr>
<td>Greater Than Equals</td>
<td><code>{&lt;key&gt;:{$gte:&lt;value&gt;}}</code></td>
<td><code>db.mycol.find({&quot;likes&quot;:{&quot;$gte:50}}).pretty()</code></td>
<td>where <code>likes &gt;= 50</code></td>
</tr>
<tr>
<td>Not Equals</td>
<td><code>{&lt;key&gt;:{$ne:&lt;value&gt;}}</code></td>
<td><code>db.mycol.find({&quot;likes&quot;:{&quot;$ne:50}}).pretty()</code></td>
<td>where <code>likes != 50</code></td>
</tr>
</tbody>
</table>

**AND in MongoDB**

Syntax:

In the `find()` method if you pass multiple keys by separating them by ',', then MongoDB treats it AND condition. Basic syntax of AND is shown below:

```
>db.mycol.find({key1:value1, key2:value2}).pretty()
```

Example

Below given example will show all the tutorials written by 'tutorials point' and whose title is 'MongoDB Overview'.

```
>db.mycol.find({"by":"tutorials point","title": "MongoDB Overview"}).pretty()
{
  "_id": ObjectID(7d78ad8902c),
  "title": "MongoDB Overview",
  "description": "MongoDB is no sql database",
  "by": "tutorials point",
  "url": "http://www.tutorialspoint.com",
  "tags": ["mongodb", "database", "NoSQL"],
  "likes": "100"
}
```
For the above given example equivalent where clause will be ‘where by='tutorials point' AND title='MongoDB Overview’’. You can pass any number of key, value pairs in find clause.

**OR in MongoDB**

Syntax:
To query documents based on the OR condition, you need to use $or keyword. Basic syntax of OR is shown below:

```javascript
>db.mycol.find(
  {
    $or: [
      {key1: value1}, {key2:value2}
    ]
  }).
.pretty()
```

Example
Below given example will show all the tutorials written by 'tutorials point' or whose title is 'MongoDB Overview'

```javascript
>db.mycol.find({$or:[{"by":"tutorials point"},{"title": "MongoDB Overview"}]}).pretty()
```
```javascript
{
  "_id": ObjectID(7df78ad8902c),
  "title": "MongoDB Overview",
  "description": "MongoDB is no sql database",
  "by": "tutorials point",
  "url": "http://www.tutorialspoint.com",
  "tags": ["mongodb", "database", "NoSQL"],
  "likes": "100"
}
>
```
Using AND and OR together

Example

Below given example will show the documents that have likes greater than 100 and whose title is either 'MongoDB Overview' or by is 'tutorials point'. Equivalent sql where clause is 'where likes>10 AND (by = 'tutorials point' OR title = 'MongoDB Overview')

```javascript
>db.mycol.find("likes": {$gt:10}, $or: [{"by": "tutorials point"},{"title": "MongoDB Overview"}]).pretty()
{
   "_id": ObjectId(7df78ad8902c),
   "title": "MongoDB Overview",
   "description": "MongoDB is no sql database",
   "by": "tutorials point",
   "url": "http://www.tutorialspoint.com",
   "tags": ["mongodb", "database", "NoSQL"],
   "likes": "100"
}
>
```
MongoDB Update Document

MongoDB's `update()` and `save()` methods are used to update document into a collection. The `update()` method update values in the existing document while the `save()` method replaces the existing document with the document passed in `save()` method.

MongoDB Update() method
The `update()` method updates values in the existing document.

Syntax:
Basic syntax of `update()` method is as follows

```
>db.COLLECTION_NAME.update(SELECTIOIN_CRITERIA, UPDATED_DATA)
```

Example
Consider the `mycol` collection has following data.

```
{ "_id" : ObjectId(5983548781331adf45ec5), "title":"MongoDB Overview"}
{ "_id" : ObjectId(5983548781331adf45ec6), "title":"NoSQL Overview"}
{ "_id" : ObjectId(5983548781331adf45ec7), "title":"Tutorials Point Overview"}
```

Following example will set the new title 'New MongoDB Tutorial' of the documents whose title is 'MongoDB Overview'

```
>db.mycol.update(\{"title":"MongoDB Overview"\},\{\$set:\"title\":"New MongoDB Tutorial"\})
>db.mycol.find()
{ "_id" : ObjectId(5983548781331adf45ec5), "title":"New MongoDB Tutorial"}
{ "_id" : ObjectId(5983548781331adf45ec6), "title":"NoSQL Overview"}
{ "_id" : ObjectId(5983548781331adf45ec7), "title":"Tutorials Point Overview"}
>
```

By default mongodb will update only single document, to update multiple you need to set a parameter 'multi' to true.

```
>db.mycol.update(\{"title":"MongoDB Overview"\},\{\$set:\"title\":"New MongoDB Tutorial"\},\{multi:true\})
```
**MongoDB Save() Method**

The `save()` method replaces the existing document with the new document passed in `save()` method.

**Syntax**

Basic syntax of `mongodb save()` method is shown below:

```javascript
>db.COLLECTION_NAME.save({_id:ObjectId(),NEW_DATA})
```

**Example**

Following example will replace the document with the `_id` '5983548781331adf45ec7'

```javascript
>db.mycol.save(

  {
    "_id" : ObjectId(5983548781331adf45ec7), "title":"Tutorials Point New Topic", "by":"Tutorials Point"
  }
)

>db.mycol.find()

{ "_id" : ObjectId(5983548781331adf45ec5), "title":"Tutorials Point New Topic", "by":"Tutorials Point"}

{ "_id" : ObjectId(5983548781331adf45ec6), "title":"NoSQL Overview"}

{ "_id" : ObjectId(5983548781331adf45ec7), "title":"Tutorials Point Overview"}

>
MongoDB Delete Document

The remove() Method

MongoDB's remove() method is used to remove document from the collection. remove() method accepts two parameters. One is deletion criteria and second is justOne flag.

1. deletion criteria: (Optional) deletion criteria according to documents will be removed.
2. justOne: (Optional) if set to true or 1, then remove only one document.

Syntax:

Basic syntax of remove() method is as follows

```javascript
>db.COLLECTION_NAME.remove(DELLETION_CRITERIA)
```

Example

Consider the mycol collection has following data.

```javascript
{
    "_id" : ObjectId(5983548781331adf45ec5), "title":"MongoDB Overview"
}
{
    "_id" : ObjectId(5983548781331adf45ec6), "title":"NoSQL Overview"
}
{
    "_id" : ObjectId(5983548781331adf45ec7), "title":"Tutorials Point Overview"
}
```

Following example will remove all the documents whose title is 'MongoDB Overview'

```javascript
>db.mycol.remove({'title':'MongoDB Overview'})
>db.mycol.find()
```

Remove only one

If there are multiple records and you want to delete only first record, then set justOne parameter in remove() method

```javascript
>db.COLLECTION_NAME.remove(DELLETION_CRITERIA,1)
```

Remove All documents

If you don't specify deletion criteria, then mongodb will delete whole documents from the collection. This is equivalent of SQL's truncate command.

```javascript
>db.mycol.remove()
>db.mycol.find()
```
MongoDB Projection

In MongoDB projection meaning is selecting only necessary data rather than selecting whole of the data of a document. If a document has 5 fields and you need to show only 3, then select only 3 fields from them.

The find() Method

MongoDB’s find() method, explained in MongoDB Query Document accepts second optional parameter that is list of fields that you want to retrieve. In MongoDB when you execute find() method, then it displays all fields of a document. To limit this you need to set list of fields with value 1 or 0. 1 is used to show the field while 0 is used to hide the field.

Syntax:

Basic syntax of find() method with projection is as follows

```javascript
>db.COLLECTION_NAME.find({}, {KEY: 1})
```

Example

Consider the collection mycol has the following data

```
{
    "_id" : ObjectId(5983548781331adf45ec5),
    "title":"MongoDB Overview"
}
{
    "_id" : ObjectId(5983548781331adf45ec6),
    "title":"NoSQL Overview"
}
{
    "_id" : ObjectId(5983548781331adf45ec7),
    "title":"Tutorials Point Overview"
}
```

Following example will display the title of the document while querying the document.

```javascript
>db.mycol.find({}, {"title":1, "_id":0})
```

```
{ "title":"MongoDB Overview"}
{ "title":"NoSQL Overview"}
{ "title":"Tutorials Point Overview"}
```

Please note _id field is always displayed while executing find() method, if you don't want this field, then you need to set it as 0.
The Limit() Method

To limit the records in MongoDB, you need to use `limit()` method. `limit()` method accepts one number type argument, which is number of documents that you want to displayed.

Syntax:

Basic syntax of `limit()` method is as follows

```javascript
> db.COLLECTION_NAME.find().limit(NUMBER)
```

Example

Consider the collection mycol has the following data

```javascript
{ "_id" : ObjectId(5983548781331adf45ec5), "title":"MongoDB Overview" }
{ "_id" : ObjectId(5983548781331adf45ec6), "title":"NoSQL Overview" }
{ "_id" : ObjectId(5983548781331adf45ec7), "title":"Tutorials Point Overview" }
```

Following example will display only 2 documents while querying the document.

```javascript
> db.mycol.find({},{"title":1,_id:0}).limit(2)
{"title":"MongoDB Overview"}
{"title":"NoSQL Overview"}
```

If you don't specify number argument in `limit()` method then it will display all documents from the collection.

**MongoDB Skip() Method**

Apart from `limit()` method there is one more method `skip()` which also accepts number type argument and used to skip number of documents.

Syntax:

Basic syntax of `skip()` method is as follows

```javascript
> db.COLLECTION_NAME.find().limit(NUMBER).skip(NUMBER)
```

Example:

Following example will only display only second document.

```javascript
> db.mycol.find({},{"title":1,_id:0}).limit(1).skip(1)
{"title":"NoSQL Overview"}
```

Please note default value in `skip()` method is 0
MongoDB Sort Documents

The sort() Method

To sort documents in MongoDB, you need to use `sort()` method. `sort()` method accepts a document containing list of fields along with their sorting order. To specify sorting order 1 and -1 are used. 1 is used for ascending order while -1 is used for descending order.

Syntax:

Basic syntax of `sort()` method is as follows

```> db.COLLECTION_NAME.find().sort({KEY:1})```

Example

Consider the collection `myycol` has the following data

```{  "_id" : ObjectId(5983548781331adf45ec5),  "title":"MongoDB Overview"}
{  "_id" : ObjectId(5983548781331adf45ec6),  "title":"NoSQL Overview"}
{  "_id" : ObjectId(5983548781331adf45ec7),  "title":"Tutorials Point Overview"}
```

Following example will display the documents sorted by title in descending order.

```> db.mycol.find({},"\{\"title\":1,\"_id\":0\}\).sort("\{\"title\":\-1\}\"
{"title":"Tutorials Point Overview"}
{"title":"NoSQL Overview"}
{"title":"MongoDB Overview"}
>```

Please note if you don’t specify the sorting preference, then `sort()` method will display documents in ascending order.
MongoDB Indexing

Indexes support the efficient resolution of queries. Without indexes, MongoDB must scan every document of a collection to select those documents that match the query statement. This scan is highly inefficient and require the mongod to process a large volume of data.

Indexes are special data structures, that store a small portion of the data set in an easy to traverse form. The index stores the value of a specific field or set of fields, ordered by the value of the field as specified in index.

The ensureIndex() Method
To create an index you need to use ensureIndex() method of mongodb.

Syntax:

Basic syntax of ensureIndex() method is as follows:

```
> db.COLLECTION_NAME.ensureIndex({KEY:1})
```

Here key is the name of field on which you want to create index and 1 is for ascending order. To create index in descending order you need to use -1.

Example

```
> db.mycol.ensureIndex("title":1))
>
```

In ensureIndex() method you can pass multiple fields, to create index on multiple fields.

```
> db.mycol.ensureIndex("title":1,"description":-1))
>
```

ensureIndex() method also accepts list of options (which are optional), whose list is given below:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>background</td>
<td>Boolean</td>
<td>Builds the index in the background so that building an index does not block other database activities. Specify true to build in the background. The default value is false.</td>
</tr>
<tr>
<td>unique</td>
<td>Boolean</td>
<td>Creates a unique index so that the collection will not accept insertion of documents where the index key or keys match an existing value in the index. Specify true to create a unique index. The default value is false.</td>
</tr>
<tr>
<td>name</td>
<td>string</td>
<td>The name of the index. If unspecified, MongoDB generates an index name by concatenating the names of the indexed fields and the sort order.</td>
</tr>
<tr>
<td>dropDups</td>
<td>Boolean</td>
<td>Creates a unique index on a field that may have duplicates. MongoDB indexes only the first occurrence of a key and removes all documents from the collection that contain subsequent occurrences of that key. Specify true to create unique index. The default value is false.</td>
</tr>
<tr>
<td>sparse</td>
<td>Boolean</td>
<td>If true, the index only references documents with the specified field. These indexes use less space but behave differently in some situations (particularly sorts). The default value is false.</td>
</tr>
<tr>
<td>expireAfterSeconds</td>
<td>integer</td>
<td>Specifies a value, in seconds, as a TTL to control how long MongoDB retains documents in this collection.</td>
</tr>
<tr>
<td>v</td>
<td>index version</td>
<td>The index version number. The default index version depends on the version of mongod running when creating the index.</td>
</tr>
<tr>
<td>weights</td>
<td>document</td>
<td>The weight is a number ranging from 1 to 99,999 and denotes the significance of the field relative to the other indexed fields in terms of the score.</td>
</tr>
<tr>
<td>default_language</td>
<td>string</td>
<td>For a text index, the language that determines the list of stop words and the rules for the stemmer and tokenizer. The default value is english.</td>
</tr>
<tr>
<td>language_override</td>
<td>string</td>
<td>For a text index, specify the name of the field in the document that contains, the language to override the default language. The default value is language.</td>
</tr>
</tbody>
</table>
MongoDB Aggregation

Aggregations operations process data records and return computed results. Aggregation operations group values from multiple documents together, and can perform a variety of operations on the grouped data to return a single result. In SQL `count(*)` and with group by is an equivalent of mongodb aggregation.

The aggregate() Method
For the aggregation in mongodb you should use `aggregate()` method.

Syntax:

Basic syntax of `aggregate()` method is as follows

```
>db.COLLECTION_NAME.aggregate(AGGREGATE_OPERATION)
```

Example:

In the collection you have the following data:
Now from the above collection if you want to display a list that how many tutorials are written by each user then you will use `aggregate()` method as shown below:

```javascript
> db.mycol.aggregate([{
  $group: {
    _id: "$by_user",
    num_tutorial: {$sum: 1}
  }
}])
{
  "result": [
    {
      "_id": "tutorials point",
      "num_tutorial": 2
    },
    {
      "_id": "tutorials point",
      "num_tutorial": 1
    }
  ],
  "ok": 1
}
```
Sql equivalent query for the above use case will be `select by_user, count(*) from mycol group by by_user`

In the above example we have grouped documents by field `by_user` and on each occurrence of `by_user` previous value of `sum` is incremented. There is a list available aggregation expressions:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>$sum</td>
<td>Sums up the defined value from all documents in the collection.</td>
<td><code>db.mycol.aggregate([{$group : {_id : &quot;$by_user&quot;, num_tutorial : {$sum : &quot;$likes&quot;}}}]</code>)</td>
</tr>
<tr>
<td>$avg</td>
<td>Calculates the average of all given values from all documents in the collection.</td>
<td><code>db.mycol.aggregate([{$group : {_id : &quot;$by_user&quot;, num_tutorial : {$avg : &quot;$likes&quot;}}}]</code>)</td>
</tr>
<tr>
<td>$min</td>
<td>Gets the minimum of the corresponding values from all documents in the collection.</td>
<td><code>db.mycol.aggregate([{$group : {_id : &quot;$by_user&quot;, num_tutorial : {$min : &quot;$likes&quot;}}}]</code>)</td>
</tr>
<tr>
<td>$max</td>
<td>Gets the maximum of the corresponding values from all documents in the collection.</td>
<td><code>db.mycol.aggregate([{$group : {_id : &quot;$by_user&quot;, num_tutorial : {$max : &quot;$likes&quot;}}}]</code>)</td>
</tr>
<tr>
<td>$push</td>
<td>Inserts the value to an array in the resulting document.</td>
<td><code>db.mycol.aggregate([{$group : {_id : &quot;$by_user&quot;, url : {$push: &quot;$url&quot;}}}]</code>)</td>
</tr>
<tr>
<td>$addToSet</td>
<td>Inserts the value to an array in the resulting document but does not create duplicates.</td>
<td><code>db.mycol.aggregate([{$group : {_id : &quot;$by_user&quot;, url : {$addToSet : &quot;$url&quot;}}}]</code>)</td>
</tr>
<tr>
<td>$first</td>
<td>Gets the first document from the source documents according to the grouping. Typically this makes only sense together with some previously applied <code>$sort</code> stage.</td>
<td><code>db.mycol.aggregate([{$group : {_id : &quot;$by_user&quot;, first_url : {$first : &quot;$url&quot;}}}]</code>)</td>
</tr>
<tr>
<td>$last</td>
<td>Gets the last document from the source documents according to the grouping. Typically this makes only sense together with some previously applied <code>$sort</code> stage.</td>
<td><code>db.mycol.aggregate([{$group : {_id : &quot;$by_user&quot;, last_url : {$last : &quot;$url&quot;}}}]</code>)</td>
</tr>
</tbody>
</table>

**Pipeline Concept**

In UNIX command shell pipeline means the possibility to execute an operation on some input and use the output as the input for the next command and so on. MongoDB also support same concept in aggregation framework. There is a set of possible stages and each of those is taken a set of documents as an input and is producing a resulting set of documents (or the final resulting JSON document at the end of the pipeline). This can then in turn again be used for the next stage and so on.

Possible stages in aggregation framework are following:

- **$project**: Used to select some specific fields from a collection.
- **$match**: This is a filtering operation and thus this can reduce the amount of documents that are given as input to the next stage.
- **$group**: This does the actual aggregation as discussed above.
- **$sort**: Sorts the documents.
- **$skip**: With this it is possible to skip forward in the list of documents for a given amount of documents.
- **$limit**: This limits the amount of documents to look at by the given number starting from the current position.
- **$unwind**: This is used to unwind document that are using arrays. when using an array the data is kind of pre-joined and this operation will be undone with this to have individual documents again. Thus with this stage we will increase the amount of documents for the next stage.
MongoDB Replication

Replication is the process of synchronizing data across multiple servers. Replication provides redundancy and increases data availability with multiple copies of data on different database servers, replication protects a database from the loss of a single server. Replication also allows you to recover from hardware failure and service interruptions. With additional copies of the data, you can dedicate one to disaster recovery, reporting, or backup.

Why Replication?
- To keep your data safe
- High (24*7) availability of data
- Disaster Recovery
- No downtime for maintenance (like backups, index rebuilds, compaction)
- Read scaling (extra copies to read from)
- Replica set is transparent to the application

How replication works in MongoDB
MongoDB achieves replication by the use of replica set. A replica set is a group of mongod instances that host the same data set. In a replica one node is primary node that receives all write operations. All other instances, secondaries, apply operations from the primary so that they have the same data set. Replica set can have only one primary node.

1. Replica set is a group of two or more nodes (generally minimum 3 nodes are required).
2. In a replica set one node is primary node and remaining nodes are secondary.
3. All data replicates from primary to secondary node.
4. At the time of automatic failover or maintenance, election establishes for primary and a new primary node is elected.
5. After the recovery of failed node, it again join the replica set and works as a secondary node.

A typical diagram of mongod replication is shown in which client application always interact with primary node and primary node then replicate the data to the secondary nodes.
Replica set features
- A cluster of N nodes
- Anyone node can be primary
- All write operations go to primary
- Automatic failover
- Automatic Recovery
- Consensus election of primary

Set up a replica set
In this tutorial we will convert standalone mongod instance to a replica set. To convert to replica set follow the below given steps:

- Shutdown already running mongodb server.

Now start the mongodb server by specifying --replSet option. Basic syntax of --replSet is given below:

```
mongod --port "PORT" --dbpath "YOUR_DB_DATA_PATH" --replSet "REPLICA_SET_INSTANCE_NAME"
```

Example
```
mongod --port 27017 --dbpath "D:\set up\mongodb\data" --replSet rs0
```
It will start a mongod instance with the name rs0, on port 27017. Now start the command prompt and connect to this mongod instance. In mongo client issue the command `rs.initiate()` to initiate a new replica set. To check the replica set configuration issue the command `rs.conf()`. To check the status of replica set issue the command `rs.status()`.

**Add members to replica set**

To add members to replica set, start mongod instances on multiple machines. Now start a mongo client and issue a command `rs.add()`.

**Syntax:**

Basic syntax of `rs.add()` command is as follows:

```
>rs.add(HOST_NAME:PORT)
```

**Example**

Suppose your mongod instance name is `mongod1.net` and it is running on port 27017. To add this instance to replica set issue the command `rs.add()` in mongo client.

```
>rs.add("mongod1.net:27017")
```

You can add mongod instance to replica set only when you are connected to primary node. To check whether you are connected to primary or not issue the command `db.isMaster()` in mongo client.
MongoDB Sharding

Sharding
Sharding is the process of storing data records across multiple machines and it is MongoDB’s approach to meeting the demands of data growth. As the size of the data increases, a single machine may not be sufficient to store the data nor provide an acceptable read and write throughput. Sharding solves the problem with horizontal scaling. With sharding, you add more machines to support data growth and the demands of read and write operations.

Why Sharding?
- In replication all writes go to master node
- Latency sensitive queries still go to master
- Single replica set has limitation of 12 nodes
- Memory can’t be large enough when active dataset is big
- Local Disk is not big enough
- Vertical scaling is too expensive

Sharding in MongoDB
Below given diagram shows the sharding in MongoDB using sharded cluster.
In the above given diagram there are three main components which are described below:

- **Shards**: Shards are used to store data. They provide high availability and data consistency. In production environment each shard is a separate replica set.

- **Config Servers**: Config servers store the cluster's metadata. This data contains a mapping of the cluster's data set to the shards. The query router uses this metadata to target operations to specific shards. In production environment sharded clusters have exactly 3 config servers.

- **Query Routers**: Query Routers are basically mongos instances, interface with client applications and direct operations to the appropriate shard. The query router processes and targets operations to shards and then returns results to the clients. A sharded cluster can contain more than one query router to divide the client request load. A client sends requests to one query router. Generally a sharded cluster have many query routers.
**MongoDB Create Backup**

**Dump MongoDB Data**

To create backup of database in mongodb you should use `mongodump` command. This command will dump all data of your server into dump directory. There are many options available by which you can limit the amount of data or create backup of your remote server.

**Syntax:**

Basic syntax of `mongodump` command is as follows

```
>mongodump
```

**Example**

Start your mongod server. Assuming that your mongod server is running on localhost and port 27017. Now open a command prompt and go to `bin` directory of your mongodb instance and type the command `mongodump`

Consider the `mycol` collection has following data.

```
>mongodump
```

The command will connect to the server running at `127.0.0.1` and port `27017` and back all data of the server to directory `/bin/dump/`. Output of the command is shown below:

```
D:\set up\mongodb\bin>mongodump
connected to: 127.0.0.1
Sat Oct 05 10:01:12.789 all dbs
Sat Oct 05 10:01:12.793 DATABASE: test to dump\test
Sat Oct 05 10:01:12.795 test.system.indexes to dump\test\system.indexes.
Sat Oct 05 10:01:12.797 test.my to dump\test\my.json
Sat Oct 05 10:01:12.800 test.my to dump\test\my.json.json
Sat Oct 05 10:01:12.803 test.my to dump\test\my.metadata.js
Sat Oct 05 10:01:12.807 test.cooll to dump\test\cooll.json
Sat Oct 05 10:01:12.810 test.cooll to dump\test\cooll.json.json
Sat Oct 05 10:01:12.812 test.cooll to dump\test\cooll.metadata.js
Sat Oct 05 10:01:12.814 test.mycol to dump\test\mycol.json
Sat Oct 05 10:01:12.817 test.mycol to dump\test\mycol.json.json
Sat Oct 05 10:01:12.819 test.mycol to dump\test\mycol.metadata.js
```

There are a list of available options that can be used with the `mongodump` command.

This command will backup only specified database at specified path.
### Syntax

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>mongodump --host HOST_NAME --port PORT_NUMBER</td>
<td>This command will backup all databases of specified mongod instance.</td>
<td>mongodump --host tutorialspoint.com --port 27017</td>
</tr>
<tr>
<td>mongodump --dbpath DB_PATH --out BACKUP_DIRECTORY</td>
<td></td>
<td>mongodump --dbpath /data/db --out /data/backup/</td>
</tr>
<tr>
<td>mongodump --collection COLLECTION --db DB_NAME</td>
<td>This command will backup only specified collection of specified database.</td>
<td>mongodump --collection mycol --db test</td>
</tr>
</tbody>
</table>

### Restore data

To restore backup data mongod's **mongorestore** command is used. This command restore all of the data from the backup directory.

**Syntax**

Basic syntax of **mongorestore** command is

```bash
>mongorestore
```

Output of the command is shown below:

![Command output](D:\setup\mongodb\bin\mongorestore connected to: 127.0.0.1 Sat Oct 05 10:05:40.922 dump\test\cool1.bson Sat Oct 05 10:05:40.924 going into namespace [test.cool1] Sat Oct 05 10:05:40.933 warning: Restoring to test.cool1 without dropping. Restored data will be inserted without raising errors; check your server log 1 objects found Sat Oct 05 10:05:41.003 Creating index: ( key: { _id: 1 }, ns: "test.cool1", name: "_id" ) Sat Oct 05 10:05:41.050 dump\test\my.bson Sat Oct 05 10:05:41.058 going into namespace [test.my] Sat Oct 05 10:05:41.062 warning: Restoring to test.my without dropping. Restored data will be inserted without raising errors; check your server log Sat Oct 05 10:05:41.063 file dump\test\my.bson empty, skipping Sat Oct 05 10:05:41.063 Creating index: ( key: { _id: 1 }, ns: "test.my", name: "_id" ) Sat Oct 05 10:05:41.065 dump\test\mycol.bson Sat Oct 05 10:05:41.072 going into namespace [test.mycol] Sat Oct 05 10:05:41.078 warning: Restoring to test.mycol without dropping. Restored data will be inserted without raising errors; check your server log 2 objects found Sat Oct 05 10:05:41.077 Creating index: ( key: { _id: 1 }, ns: "test.mycol", name: "_id" ) Sat Oct 05 10:05:41.079 Creating index: ( key: { name: 1 }, ns: "test.mycol", name: "name_1" )
When you are preparing a MongoDB deployment, you should try to understand how your application is going to hold up in production. It’s a good idea to develop a consistent, repeatable approach to managing your deployment environment so that you can minimize any surprises once you’re in production.

The best approach incorporates prototyping your set up, conducting load testing, monitoring key metrics, and using that information to scale your set up. The key part of the approach is to proactively monitor your entire system - this will help you understand how your production system will hold up before deploying, and determine where you will need to add capacity. Having insight into potential spikes in your memory usage, for example, could help put out a write-lock fire before it starts.

To monitor your deployment MongoDB provides some commands that are shown below:

**mongostat**

This command checks the status of all running mongod instances and return counters of database operations. These counters include inserts, queries, updates, deletes, and cursors. Command also shows when you’re hitting page faults, and showcase your lock percentage. This means that you’re running low on memory, hitting write capacity or have some performance issue.

To run the command start your mongod instance. In another command prompt go to bin directory of your mongodb installation and type mongostat.

```
D:\set up\mongodb\bin>mongostat
```

Output of the command is shown below:
mongotop

This command track and report the read and write activity of MongoDB instance on a collection basis. By default mongotop return information in each second, by you can change it accordingly. You should check that this read and write activity matches your application intention, and you’re not firing too many writes to the database at a time, reading too frequently from disk, or are exceeding your working set size.

To run the command start your mongod instance. In another command prompt go to bin directory of your mongodb installation and type mongotop.

D:\set up\mongodb\bin>mongotop

Output of the command is shown below:
To change `mongotop` command to return information less frequently specify a specific number after the `mongotop` command.

```
D:\set up\mongodb\bin>mongotop 30
```

The above example will return values every 30 seconds.

Apart from the `mongodb` tools, 10gen provides a free, hosted monitoring service MongoDB Management Service (MMS), that provides a dashboard and gives you a view of the metrics from your entire cluster.
**MongoDB Java**

**Installation**
Before we start using MongoDB in our Java programs, we need to make sure that we have MongoDB JDBC Driver and Java set up on the machine. You can check Java tutorial for Java installation on your machine. Now, let us check how to set up MongoDB JDBC driver.

- You need to download the jar from the path [Download mongo.jar](#). Make sure to download latest release of it.
- You need to include the `mongo.jar` into your classpath.

**Connect to database**
To connect database, you need to specify database name, if database doesn’t exist then mongodb creates it automatically.

Code snippets to connect to database would be as follows:

```java
import com.mongodb.MongoClient;
import com.mongodb.MongoException;
import com.mongodb.WriteConcern;
import com.mongodb.DB;
import com.mongodb.DBCollection;
import com.mongodb.BasicDBObject;
import com.mongodbDBObject;
import com.mongodb.DBCursor;
import com.mongodb.ServerAddress;
import java.util.Arrays;

public class MongoDBJDBC{
    public static void main( String args[] ){
        try{
            // To connect to mongodb server
            MongoClient mongoClient = new MongoClient( "localhost" , 27017 );
            // Now connect to your databases
            DB db = mongoClient.getDB( "test" );
            System.out.println("Connect to database successfully");
            boolean auth = db.authenticate(myUserName, myPassword);
            System.out.println("Authentication:" +auth);
        catch(Exception e){
            System.err.println( e.getClass().getName() +": " + e.getMessage() );
        }}}}
Now, let's compile and run above program to create our database test. You can change your path as per your requirement. We are assuming current version of JDBC driver mongo-2.10.1.jar is available in the current path.

```bash
$javac MongoDBJDBC.java
$java -classpath ".:mongo-2.10.1.jar" MongoDBJDBC
Connect to database successfully
Authentication: true
```

If you are going to use Windows machine, then you can compile and run your code as follows:

```bash
$javac MongoDBJDBC.java
$java -classpath ".;mongo-2.10.1.jar" MongoDBJDBC
Connect to database successfully
Authentication: true
```

Value of `auth` will be true, if the user name and password are valid for the selected database.

**Create a collection**

To create a collection, `createCollection()` method of `com.mongodb.DB` class is used.

Code snippets to create a collection:

```java
import com.mongodb.MongoClient;
import com.mongodb.MongoException;
import com.mongodb.WriteConcern;
import com.mongodb.DB;
import com.mongodb.DBCollection;
import com.mongodb.BasicDBObject;
import com.mongodb.DBCursor;
import com.mongodb.ServerAddress;
import java.util.Arrays;

public class MongoDBJDBC{
  public static void main( String args[] ) {
    try{
      // To connect to mongodb server
      MongoClient mongoClient = new MongoClient( "localhost", 27017 );
      // Now connect to your databases
      DB db = mongoClient.getDB( "test" );
      System.out.println("Connect to database successfully");
      boolean auth = db.authenticate(myUserName, myPassword);
      System.out.println("Authentication: "+auth);
      DBCollection coll = db.createCollection("mycol");
      System.out.println("Collection created successfully");
    }catch(Exception e){
      System.err.println( e.getClass().getName() + ": " + e.getMessage() );
    }
  }
}
```
When program is compiled and executed, it will produce the following result:

<table>
<thead>
<tr>
<th>Connect to database successfully</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authentication: true</td>
</tr>
<tr>
<td>Collection created successfully</td>
</tr>
</tbody>
</table>

## Getting/ selecting a collection

To get/select a collection from the database, `getCollection()` method of `com.mongodb.DBCollection` class is used.

Code snippets to get/select a collection:

```java
import com.mongodb.MongoClient;
import com.mongodb.MongoException;
import com.mongodb.WriteConcern;
import com.mongodb.DB;
import com.mongodb.DBCollection;
import com.mongodb.BasicDBObject;
import com.mongodb.DBCollection;
import com.mongodb.DBCursor;
import com.mongodb.ServerAddress;
import java.util.Arrays;

public class MongoDBJDBC{
    public static void main( String args[] ){
        try{
            // To connect to mongodb server
            MongoClient mongoClient = new MongoClient( "localhost" , 27017 );
            // Now connect to your databases
            DB db = mongoClient.getDB( "test" );
            System.out.println("Connect to database successfully");
            boolean auth = db.authenticate(myUserName, myPassword);
            System.out.println("Authentication: "+auth);
            DBCollection coll = db.getCollection("mycol");
            System.out.println("Collection mycol selected successfully");
        }catch(Exception e){
            System.err.println( e.getClass().getName() + ": " + e.getMessage() );
        }
    }
}
```
When program is compiled and executed, it will produce the following result:

Connect to database successfully
Authentication: true
Collection created successfully
Collection mycol selected successfully

Insert a document
To insert a document into mongodb, `insert()` method of `com.mongodb.DBCollection` class is used.

Code snippets to insert a document:

```java
import com.mongodb.MongoClient;
import com.mongodb.MongoException;
import com.mongodb.WriteConcern;
import com.mongodb.DB;
import com.mongodb.DBCollection;
import com.mongodb.BasicDBObject;
import com.mongodb.DBCursor;
import com.mongodb.DBObject;
import com.mongodb.ServerAddress;
import java.util.Arrays;

public class MongoDBJDBC{
    public static void main( String args[] ){
        try{
            // To connect to mongodb server
            MongoClient mongoClient = new MongoClient( "localhost" , 27017 );
            // Now connect to your databases
            DB db = mongoClient.getDB( "test" );
            System.out.println("Connect to database successfully");
            boolean auth = db.authenticate(myUserName, myPassword);
            System.out.println("Authentication: "+auth);
            DBCollection coll = db.getCollection("mycol");
            System.out.println("Collection mycol selected successfully");
            BasicDBObject doc = new BasicDBObject("title", "MongoDB").
                append("description", "database").
                append("by", "tutorials point");
            coll.insert(doc);
            System.out.println("Document inserted successfully");
        }catch(Exception e){
            System.err.println( e.getClass().getName() + " : " + e.getMessage() );
        }
    }
}
```

When program is compiled and executed, it will produce the following result:
Connect to database successfully
Authentication: true
Collection mycol selected successfully
Document inserted successfully

Retrieve all documents
To select all documents from the collection, find() method of com.mongodb.DBCollection class is used. This method returns a cursor, so you need to iterate this cursor.

Code snippets to select all documents:

```java
import com.mongodb.MongoClient;
import com.mongodb.MongoException;
import com.mongodb.WriteConcern;
import com.mongodb.DB;
import com.mongodb.DBCollection;
import com.mongodb.BasicDBObject;
import com.mongodb.DBCursor;
import com.mongodb.ServerAddress;
import java.util.Arrays;

public class MongoDBJDBC {
    public static void main( String[] args ) {
        try {
            // To connect to mongodb server
            MongoClient mongoClient = new MongoClient( "localhost", 27017 );
            // Now connect to your databases
            DB db = mongoClient.getDB( "test" );
            System.out.println("Connect to database successfully");
            boolean auth = db.authenticate(myUserName, myPassword);
            System.out.println("Authentication: "+auth);
            DBCollection coll = db.getCollection("mycol");
            System.out.println("Collection mycol selected successfully");
            DBCursor cursor = coll.find();
            int i=1;
            while (cursor.hasNext()) {
                System.out.println("Inserted Document: "+i);
                System.out.println(cursor.next());
                i++;
            }
        } catch (Exception e) {
            System.err.println( e.getClass().getName() + ": " + e.getMessage() );
        }
    }
}
```

When program is compiled and executed, it will produce the following result::
Connect to database successfully
Authentication: true
Collection mycol selected successfully
Inserted Document: 1
{
    "_id" : ObjectId("7df78ad8902c"),
    "title": "MongoDB",
    "description": "database",
    "likes": 100,
    "url": "http://www.tutorialspoint.com/mongodb/",
    "by": "tutorialspoint"
}

Update document
To update document from the collection, update() method of com.mongodb.DBCollection class is used.

Code snippets to select first document:

```java
import com.mongodb.MongoClient;
import com.mongodb.MongoException;
import com.mongodb.WriteConcern;
import com.mongodb.DB;
import com.mongodb.DBCollection;
import com.mongodb.BasicDBObject;
import com.mongodb.DBOid;
import com.mongodb.DBCursor;
import java.util.Arrays;

public class MongoDBJDBC {
    public static void main(String[] args) {
        try {
            // To connect to mongodb server
            MongoClient mongoClient = new MongoClient("localhost", 27017);
            // Now connect to your databases
            DB db = mongoClient.getDB("test");
            System.out.println("Connect to database successfully");
            boolean auth = db.authenticate(myUserName, myPassword);
            System.out.println("Authentication: " + auth);
            DBCollection coll = db.getCollection("mycol");
            System.out.println("Collection mycol selected successfully");
        }
    }
}
```
DBCursor cursor = coll.find();
while (cursor.hasNext()) {
    DBObj updateDocument = cursor.next();
    updateDocument.put("likes", 200)
    col1.update(updateDocument);
}  
System.out.println("Document updated successfully");
cursor = coll.find();
int i=1;
while (cursor.hasNext()) {
    System.out.println("Updated Document: "+i);
    System.out.println(cursor.next());
i++;
}
}catch(Exception e){
    System.err.println( e.getClass().getName() + ": " + e.getLocalizedMessage() );
}
}

When program is compiled and executed, it will produce the following result:

Connect to database successfully
Authentication: true
Collection mycol selected successfully
Document updated successfully
Updated Document: 1
{
  
  "id" : ObjectId(7df78ad8902c),
  "title": "MongoDB",
  "description": "database",
  "likes": 100,
  "url": "http://www.tutorialspoint.com/mongodb",
  "by": "tutorials point"
}
Delete first document

To delete first document from the collection, you need to first select the documents using `findOne()` method and then `remove` method of `com.mongodb.DBCollection` class.

Code snippets to delete first document:

```java
import com.mongodb.MongoClient;
import com.mongodb.MongoException;
import com.mongodb.WriteConcern;
import com.mongodb.DB;
import com.mongodb.DBCollection;
import com.mongodb.BasicDBObject;
import com.mongodbDBObject;
import com.mongodb.DBCursor;
import com.mongodb.MongoClient;
import java.util.Arrays;

public class MongoDBJDBC{
    public static void main(String args[])
        try{
            // To connect to mongodb server
            MongoClient mongoClient = new MongoClient( "localhost" , 27017 );
            // Now connect to your databases
            DB db = mongoClient.getDB( "test" );
            System.out.println("Connect to database successfully");
            boolean auth = db.authenticate(myUserName, myPassword);
            System.out.println("Authentication: "+auth);
            DBCollection coll = db.getCollection("mycol");
            System.out.println("Collection mycol successfully");
            DBObject myDoc = coll.findOne();
            col1.remove(myDoc);
            DBCursor cursor = coll.find();
            int i=1;
            while (cursor.hasNext()) {
                System.out.println("Inserted Document: "+i);
                System.out.println(cursor.next());
                i++;
            }
            System.out.println("Document deleted successfully");
            catch(Exception e) {
                System.err.println( e.getClass().getName() + ": "+ e.getMessage() );
            }
        }
    }
}
When program is compiled and executed, it will produce the following result:

<table>
<thead>
<tr>
<th>Connect to database successfully</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authentication: true</td>
</tr>
<tr>
<td>Collection mycol selected successfually</td>
</tr>
<tr>
<td>Document deleted successfully</td>
</tr>
</tbody>
</table>

Remaining mongodb methods `save()`, `limit()`, `skip()`, `sort()` etc works same as explained in subsequent tutorial.
To use mongodb with php you need to use mongodb php driver. Download the driver from the url [Download PHP Driver](#). Make sure to download latest release of it. Now unzip the archive and put php_mongo.dll in your PHP extension directory (“ext” by default) and add the following line to your php.ini file:

```php
extension=php_mongo.dll
```

**Make a connection and Select a database**

To make a connection, you need to specify database name, if database doesn’t exist then mongodb creates it automatically.

Code snippets to connect to database would be as follows:

```php
<?php
    // connect to mongodb
    $m = new MongoClient();
    echo "Connection to database successfully";
    // select a database
    $db = $m->mydb;
    echo "Database mydb selected";
?>
```

When program is executed, it will produce the following result::

```
Connection to database successfully
Database mydb selected
```

**Create a collection**

Code snippets to create a collection would be as follows:

```php
<!-- code to create a collection -->
```
// connect to mongodb
$m = new MongoClient();
echo "Connection to database successfully";
// select a database
$db = $m->mydb;
echo "Database mydb selected";
$collection = $db->createCollection("mycol");
echo "Collection created successfully";
?>

When program is executed, it will produce the following result:

Connection to database successfully
Database mydb selected
Collection created successfully

Insert a document

To insert a document into mongodb, insert() method is used.

Code snippets to insert a document:

```php
<?php
// connect to mongodb
$m = new MongoClient();
echo "Connection to database successfully";
// select a database
$db = $m->mydb;
echo "Database mydb selected";
$collection = $db->mycol;
echo "Collection selected successfully";
$document = array(
    "title" => "MongoDB",
    "description" => "database",
    "likes" => 100,
    "url" => "http://www.tutorialspoint.com/mongodb",
    "by" => "tutorials point"
);
$collection->insert($document);
echo "Document inserted successfully";
?>
```

When program is executed, it will produce the following result:
Connection to database successfully
Database mydb selected
Collection selected successfully
Document inserted successfully

**Find all documents**

To select all documents from the collection, find() method is used.

Code snippets to select all documents:

```php
<?php
    // connect to mongodb
    $m = new MongoClient();
    echo "Connection to database successfully";
    // select a database
    $db = $m->mydb;
    echo "Database mydb selected";
    $collection = $db->mycol;
    echo "Collection selected successfully";

    $cursor = $collection->find();
    // iterate cursor to display title of documents
    foreach ($cursor as $document) {
        echo $document['title'] . "n";
    }
?>
```

When program is executed, it will produce the following result:

Connection to database successfully
Database mydb selected
Collection selected successfully

```
{
    "title": "MongoDB"
}
```

**Update a document**

To update a document, you need to use update() method.

In the below given example we will update the title of inserted document to MongoDB Tutorial. Code snippets to update a document:
<?php
    // connect to mongodb
    $m = new MongoClient();
    echo "Connection to database successfully";
    // select a database
    $db = $m->mydb;
    echo "Database mydb selected";
    $collection = $db->mycol;
    echo "Collection selected successfully";

    // now update the document
    $collection->update(array("title"=>"MongoDB"), array("$set"=>array("title"=>"MongoDB Tutorial")));
    echo "Document updated successfully";
    // now display the updated document
    $cursor = $collection->find();
    // iterate cursor to display title of documents
    echo "Updated document";
    foreach ($cursor as $document) {
        echo $document["title"] . "n";
    }
?>

When program is executed, it will produce the following result:

Connection to database successfully
Database mydb selected
Collection mycol selected successfully
Document updated successfully
Updated document
{ "title": "MongoDB Tutorial" }

Delete a document

To delete a document, you need to use remove() method.

In the below given example we will remove the documents that has title MongoDB Tutorial. Code snippets to delete document:
<?php

// connect to mongodb
$m = new MongoClient();
echo "Connection to database successfully";
// select a database
$db = $m->mydb;
echo "Database mydb selected";
$collection = $db->mycol;
echo "Collection selected successfully";

// now remove the document
$collection->remove(array("title"=>'MongoDB Tutorial'),false);
echo "Documents deleted successfully";

// now display the available documents
$cursor = $collection->find();
// iterate cursor to display title of documents
echo "Updated document";
foreach ($cursor as $document) {
    echo $document["title"] . "n";
}
?>

When program is executed, it will produce the following result:

- Connection to database successfully
- Database mydb selected
- Collection selected successfully
- Documents deleted successfully

In the above given example second parameter is boolean type and used for justOne field of remove() method.

Remaining mongodb methods findOne(), save(), limit(), skip(), sort() etc works same as explained in above tutorial.
